A Cinética Química das Reações de Combustão

A.1 Estado da Arte

A combustão de hidrocarbonetos com o ar envolve um número considerável de etapas (iniciação, propagação, transferência de cadeia e terminação) com a presença de espécies intermediários (também chamados de radicais) antes da formação final de produtos (Law, 2006). A cinética química - ou mecanismo - das reações de combustão determina o tempo que um sistema leva para atingir o estado final de equilíbrio (Versteeg e Malalasekera, 2007).

Idealmente, um mecanismo de cinética química deve ser capaz de descrever a oxidação do combustível em uma ampla faixa de condições de operação (temperatura, pressão, riqueza, etc.) e para uma ampla gama de sistemas simples, tais como reatores de fluxo contínuo, tubos de choque, chamas de difusão, chamas pré-misturadas, etc. (Curran *et al.*, 2004).

As taxas de consumo dos reagentes e formação dos produtos de combustão aparecem no termo fonte da equação de transporte das espécies químicas que participam em uma reação de combustão. Considera-se apenas a k-ésima reação elementar reversível descrita por

$$\sum_{i=1}^{N} \nu'_{ik} \mathcal{M}_i \Leftrightarrow \sum_{i=1}^{N} \nu''_{ik} \mathcal{M}_i, \quad k = 1, 2, ..., K,$$
(A-1)

onde $\nu'_{ik} \in \nu''_{ik}$ são os coeficientes estequiométricos das espécies químicas, \mathcal{M}_i . A taxa de progresso da *k*-ésima reação elementar pode ser escrita como o produto dos coeficientes de todas as N espécies químicas participantes na *k*ésima reação elementar,

$$\dot{q}_{k} = k_{k}^{f} \prod_{i=1}^{N} \left[\mathcal{M}_{i}\right]^{\nu_{ik}'} - k_{k}^{b} \prod_{i=1}^{N} \left[\mathcal{M}_{i}\right]^{\nu_{ik}''}, \qquad (A-2)$$

onde k_k^f e k_k^b representam respectivamente os coeficientes direito e reverso da velocidade da k-ésima reação e $[\mathcal{M}_i]$ é a concentração da espécie \mathcal{M}_i ,

$$[\mathcal{M}_i] \equiv [X_i] = \frac{\rho_i Y_i}{\overline{MW}},\tag{A-3}$$

onde \overline{MW} é o peso molecular da mistura. O coeficiente da velocidade direito da k-ésima reação é expresso pela lei de Arrhenius,

$$k_k^f = A_k T_k^m \exp\left(-\frac{E_{Ak}}{RT}\right),\tag{A-4}$$

onde R é a constante universal dos gases (8, 3143 kJ/mol-K), A_k , m_k e E_{Ak} são, para cada reação elementar, o fator pré-exponencial de Arrhenius, o expoente da temperatura e a energia de ativação. O coeficiente reverso da k-ésima reação é obtido a partir da constante de equilíbrio, Kc_k , definida como,

$$Kc_{k} = \frac{k_{k}^{f}}{k_{k}^{b}} = \prod_{i=1}^{N} \left[\mathcal{M}_{i} \right]^{(\nu_{ik}^{"} - \nu_{ik}^{'})}.$$
 (A-5)

A conversão da *i*-ésima espécie química na *k*-ésima reação elementar, $\dot{q}_{ik} = d[\mathcal{M}_{ik}]/dt$, é definida como,

$$\dot{q}_{ik} = \frac{d[\mathcal{M}_{ik}]}{dt} = \left(\nu_{ik}^{''} - \nu_{ik}^{'}\right)\dot{q}_{k} = \left(\nu_{ik}^{''} - \nu_{ik}^{'}\right)\left[k_{k}^{f}\prod_{i=1}^{N}\left[\mathcal{M}_{i}\right]^{\nu_{ik}^{'}} - k_{k}^{b}\prod_{i=1}^{N}\left[\mathcal{M}_{i}\right]^{\nu_{ik}^{''}}\right],\tag{A-6}$$

logo, a taxa de produção química da *i*-ésima espécie, $\dot{\omega}_i$, é escrita como,

$$\dot{\omega}_i = \overline{MW}_i \sum_{k=1}^{K} \dot{q}_{ik}, \qquad (A-7)$$

onde W_i é o peso molecular da *i*-ésima espécie química.

A.2 Mecanismos de Cinética Química Detalhada

Atualmente, existem mecanismos detalhados de cinética química razoavelmente confiáveis que estão disponíveis para combustíveis simples tais como o hidrogênio [Li *et al.*, (2004); O Conaire *et al.*, (2004); Konnov (2008), etc.] e metano [GRI-Mech 3.0 (Smith *et al.*, 1999); Leeds 1.5, (Hughes *et al.*,2001); San Diego 20111122, etc.], cuja faixa de validade é bem estabelecida. Trabalhos recentes permitem, descrever os processos da combustão com ar de hidrocarbonetos envolvendo até quatro átomos de carbono tais propano, butano, metanol e etanol. No entanto, a faixa de validade é tão mais restrita quanto maior a complexidade da estrutura química-molecular do combustível.

São objetos de desenvolvimentos recentes mecanismos detalhados de cinética para a modelagem da combustão de hidrocarbonetos representativos a combustíveis líquidos, como gasolina, querosene e Diesel. Estes mecanismos envolvem um número considerável de espécies químicas e reações elementares, o que difculta a tarefa de empregá-los em uma simulação numérica.

O aparecimento de computadores com grande capacidade de processamento e armazenamento de dados, e a derivação de algoritmos numéricos acurados para a resolução de equações cinéticas simultâneas contribuiram decisivamente para o desenvolvimento de mecanismos, os quais requerem de valores de propriedades termoquímicas fundamentais para poderem ser utilizados, tais como, a energia de ativação, coeficiente de frequência de colisão, etc.

Espera-se que em um futuro próximo, os mecanismos de cinética química da oxidação dos principais hidrocarbonetos de interesse industrial, permitam predizer, com uma boa exatidão, os diferentes fenômenos aerotermoquímicos relacionados à combustão.

A seguir, listam-se dois mecanismos de cinética química detalhada que foram empregados nas simulações de combustão turbulenta nos queimadores de Endrud (2000) e Nakamura *et al.* (2011)

A.2.1 Mecanismo GRI-Mech 3.0

O Mecanismo GRI-Mech 3.0, que possui 325 reações químicas elementais e 53 espécies químicas, foi utilizado para gerar a biblioteca de elementos de chama que é utilizada para a simulação da combustão turbulenta do propano com o oxigênio enriquecido com ar.

A.2.2 Mecanismo Wisconsin

O mecanismo de Wisconsisn foi o único capaz de gerar a biblioteca de elementos de chama que necessita o FluentTM para a simulação da combustão turbulenta do n-heptano (surrogate do querosene) com o oxigênio. Isto foi possível, devido ao baixo número de reações e espécies químicas deste mecanismo "esqueleto".

Dados de Entrada e Saída do Programa Radcal e Interface em UDF para o Acoplamento Radcal/FluentTM

A seguir, será detalhada a especificação dos parâmetros de entrada no arquivo de entrada RC.dat, de forma que o Radcal calcule a intensidade da radiação espectral e as demais propriedades radiantes espectrais. Da mesma forma, serão descritos os parâmetros de saída e a maneira como o Radcal imprime no arquivo de saída RCOUT.dat, quando um processamento é bem sucedido.

B.1 Parâmetros de Entrada

Os dados de entrada são fornecidos no arquivo RC.dat, o qual possui formato livre. Nele, é permitido, na primeira linha, a entrada de um dado que representa o número de elementos, NPT, (cujo máximo 50), no qual o caminho óptico, s, é dividido.

A segunda linha lista o tamanho do primeiro elemento DD(1) em metros, seguido pela sua temperatura T(1) em Kelvin, e as pressões parciais (em kPa) do dióxido de carbono, PP(1,1), vapor de água, PP(1,2), metano, PP(1,3), monóxido de carbono, PP(1,4), oxigênio, PP(1,5) e nitrogênio, PP(1,6). A última entrada na segunda linha corresponde à fração volumétrica da fuligem no primeiro elemento, W(1). É importante ressaltar que o primeiro elemento é localizado no ponto do espaço em que a intensidade da radiação espectral é desejada, e não na vizinhança do volume computacional.

A terceira linha contém informações análogas à primeira, porém, para o segundo elemento, e assim por diante, para todos os NPT elementos. Finalmente, na linha NPT+2 são fornecidos a temperatura da parede, TWALL, e os números de onda mínimo e máximo (em cm⁻¹), OMMIN e OMMAX. Cabe ressaltar que as propriedades radiantes dos gases e a fuligem para números de onda, ω , menores que 50 cm⁻¹ ou maiores que 10000 cm⁻¹ são negligenciados.

A Figura B.1 mostra uma representação esquemática da maneira como o software Radcal discretiza o domínio espacial, e como os parâmetros de entrada são localizados, tanto para um sistema não homogêneno, como para o

Apêndice B. Dados de Entrada e Saída do Programa Radcal e Interface em UDF para o Acoplamento Radcal/FluentTM 267

Figura B.1: Discretização considerada pelo programa Radcal para: (a) sistemas não homogêneos e (b) sistemas homogêneos e isotérmicos.

caso de um sistema homogêneo e isotérmico. Para fins de exemplo, apresentamse dados que são fornecidos ao arquivo RC.dat como parâmetros de entrada necessários para cálculos relativos à radiação espectral, para ambos os tipos de sistemas, homogêneos e não homogêneos.

B.1.1 RC.dat – Arguivo de Entrada do Radcal

A seguir, mostram-se dois exemplos de dados de entrada, os quais descrevem as condições iniciais de problemas típicos que o Radcal é capaz de resolver. Estes dados de entrada foram retirados do relatório técnico 1042 da NIST (Grosshandler, 1993)

Como se pode perceber na Tabela B.1, a primeira linha indica o número de elementos. Neste exemplo, o valor de 1 denota um problema de radiação térmica de uma meio participante homogêneo e isotérmico. Na segunda linha, a primeira coluna é a espessura óptica do elemento, L = 0,5 m. Na terceira coluna é colocada a temperatura do meio, 320 K, As colunas seguintes correspondem aos dados de entrada das pressões parciais de dióxido de carbono, vapor de água, monóxido de carbono, oxigênio, nitrogênio iguais a 0,001, 0,001, 0,001, 0,001, 20,20 e 80,80 kPa, respectivamente, e à fração Apêndice B. Dados de Entrada e Saída do Programa Radcal e Interface em UDF para o Acoplamento Radcal/FluentTM 268

Tabela B.1: Dados de entrada típicos do arquivo RC.dat para o caso de um sistema isotérmico e homogêneo (Grosshandler, 1993).

volumétrica da fuligem, que é de $1, 0 \times 10^{-8}$. Na terceira linha, a primeira coluna é a temperatura da parede, 0 K, enquanto que nas segunda e a terceira colunas encontram-se os números de onda, $\omega = \lambda^{-1}$, mínimo e máximo, 400 e 8000 cm⁻¹, respectivamente. Finalmente na quarta linha o valor 0 indica o fim do arquivo.

Tabela B.2: Dados de entrada típicos do arquivo RC.dat para o caso de um sistema não-isotérmico (Grosshandler, 1993).

O arquivo de entrada mostrado na Tabela B.2 para o caso de um meio não homogêneo e não isotérmico é similar àquele da Tabela B.1 para um meio homogêneo e isotérmico. De forma geral, as linhas apresentadas nas Tabelas B.1 e B.2 correspondem a,

- Linha 1: número de elementos homogêneos.
- Linha 2: comprimento da célula (m), temperatura (K), pressões parciais de CO_2 (kPa), H_2O (kPa), CH_4 (kPa), CO (kPa), O_2 (kPa), N_2 (kPa) e fuligem (kPa).
- Linhas 3 até n + 1: similar à linha 2 para o resto dos elementos.
- Linha n + 2: temperatura da parede (K), comprimento de onda mínimo (cm⁻¹), comprimento de onda máximo (cm⁻¹).
- Linha n+3: critério de fim do arquivo (igual a 0), ou número de elementos homogêneos para o caso seguinte.

B.2 Parâmetros de Saída

Os resultados do cálculo realizado pelo Radcal podem ser encontrados no arquivo de saída RCOUT.DAT, onde as condições de entrada fornecidas no arquivo RC.dat, são resumidas em forma tabelada, seguido pelo fluxo total de energia radiante, com unidades de W/m² sr, que incide sobre o centro do elemento 1.

Assim, a intensidade de radiação espectral, (QW(K) para I_{λ}), e a transmitância (ou trasmissividade) espectral, (TTAU(K) para τ_{λ}) são listadas para cada comprimento de onda (LAMBDA(K) para λ). O número de comprimentos de onda calculados é limitado a 600, e os intervalos de comprimentos de onda variam entre 0,005 μ m a 1 μ m e 18,2 μ m a 200 μ m.

Para o caso especial de caminho óptico uniforme (avaliado sobre o comprimento médio do feixe, L_m), o Radcal, além de calcular a intensidade espectral e a trasmissividade espectral em todo o dominio de comprimento de onda prescrito, também calcula o coeficiente médio de absorção incidente, $a_I(L_m)$, o coeficiente médio de emissão de Planck, $a_P(L_m)$, e o coeficiente médio de absorção/emissão efetivo, $a_E(L_m)$. O Anexo B.2.1 mostra resultados típicos calculados pelo Radcal para os dados de entrada colocados no Anexo B.1.1

B.2.1 RCOUT.dat – Arquivo de Saída Criado pelo Radcal Apôs a Simulação

A Figura B.2 apresenta mediante o arquivo RCOUT.dat, os resultados típicos calculados pelo Radcal, das propriedades radiantes da mistura isotérmica e homogênea descrita pela Tabela B.1.

A transmitância espectral, função do comprimento de onda, é mostrada na Figura B.3, cujos dados foram obtidos daqueles apresentados no arquivo RCOUT.dat da Figura B.1. Apêndice B. Dados de Entrada e Saída do Programa Radcal e Interface em UDF para o Acoplamento Radcal/FluentTM 270

D Coeficiente de Absorção Espectral da Fuligem Segundo a Teoria de Rayleigh – Formulação e Programação em UDF

D.1

Teoria de Absorção/Espalhamento de Rayleigh para o Cálculo das Propriedades Radiantes da Fuligem

Tal como foi apresentado no Capítulo 3, o coeficiente de absorção espectral para a fuligem, segundo a teoria de espalhamento Mie na aproximação Rayleigh, é definido como,

$$a_{soot,\lambda} = \frac{36\pi nq}{\left(n^2 - q^2 + 2\right)^2 + 4n^2q^2} \frac{f_V}{\lambda} = C_\lambda \frac{f_V}{\lambda},$$
 (D-1)

sendo que,

$$C_{\lambda} = \frac{36\pi nq}{\left(n^2 - q^2 + 2\right)^2 + 4n^2q^2}.$$
 (D-2)

Estas expressões são válidas quando $d_p \ll \lambda$, o que é o caso para partículas de fuligem. Segundo a Equação (D-2), C_{λ} representa uma expressão que depende da parte real e imaginária do índice de refração, m = n + qi, que por sua vez, depende do comprimento de onda. Chang e Charalampopoulos (1990) caracterizaram a dependência de $n \in q$ com o comprimento de onda. A relação funcional empírica de $n \in q$ com λ obtida por estes autores é,

$$n = 1,811 + 0,1263 \ln \lambda + 0,270 \ln^2 \lambda + 0,0417 \ln^3 \lambda,$$
 (D-3)

$$q = 0,5821 + 0,1213 \ln \lambda + 0,2309 \ln^2 \lambda - 0,0100 \ln^3 \lambda,$$
 (D-4)

cuja aplicação é indicada nas faixas de comprimentos de onda $\lambda \in [0, 4, 30] \mu m$.

D.2

Cálculo do Coeficiente de Absorção Equivalente da Fuligem Através da Teoria de Rayleigh e Aplicando-se a Metodologia de Discretização Valor Médio

Uma vez que o Fluent aceita, para cada faixa de comprimento de onda, apenas um valor constante do coeficiente de absorção, $\overline{a}_{soot,j}$ ($j = 1, 2, ..., N_b$),

Figura D.1: Curva do coeficiente de absorção espectral da fuligem segundo a teoria de espalhamento Rayleigh e seu equivalente aplicando a abordagem de Modelo de Banda Larga-Cinza (GWB).

precisa-se implementar, via UDF, a conversão de $a_{soot,\lambda}$ [Equação (D-1)], em seu análogo discreto. Para isto é aplicada a abordagem de Modelo Banda Larga-Cinza (*Gray Wide Band Model*, GWB), que estabelece, para uma faixa de comprimento de onda delimitada por $\lambda_j \in \lambda_{j+1}$, um coeficiente de absorção equivalente, $\overline{a}_{soot,j}$. Aplicando metodologia de discretização de "valor médio", obtem-se a seguinte expresão,

$$\overline{a}_{soot,j} = \frac{1}{\Delta\lambda_j} \int_{\lambda_j}^{\lambda_{j+1}} \frac{C_{\lambda} f_V}{\lambda^{-1}} d\lambda = \frac{C_{o,j} f_V}{\lambda_{j+1} - \lambda_j} \int_{\lambda_j}^{\lambda_{j+1}} \lambda^{-1} d\lambda, \qquad (D-5)$$

onde $\Delta \lambda_j = \lambda_{j+1} - \lambda_j$. Nota-se que f_V independe do comprimento de onda e que, por conveniência, o valor de C_{λ} é equivalente a $C_{o,j}$, o que será assumido por simplicidade, como sendo constante para cada faixa cinza. A Figura D.1 ilustra este procedimento de cálculo do coeficiente de absorção equivalente da fuligem, $\overline{a}_{soot,j}$, para cada *j*-ésima faixa de comprimento de onda.

A resolução da Equação (D-5) fornece o seguinte resultado para o coeficiente de absorção equivalente para a j-ésima faixa "cinza",

$$\overline{a}_{soot,j} = \frac{C_{o,j} f_V \ln\left(\frac{\lambda_{j+1}}{\lambda_j}\right)}{\lambda_{j+1} - \lambda_j},\tag{D-6}$$

sendo que,

$$C_{o,j} = C_{\lambda}(\lambda_j), \tag{D-7}$$

que é resolvido com o emprego das Equações. (D-2), (D-3) e (D-4). Note-se que a Equação (D-6) pode ser reescrita, para cada *j*-ésima banda "cinza", como,

j	$\lambda_j - \lambda_{j+1} \; (\mu \mathrm{m})$	$C_{o,j}$	K_j
1	1,00 - 2,62	4.13	2456402.11
2	$2,\!62-2,\!94$	4.22	1519286.56
3	2,94 - 3.57	4.11	1267099.34
4	$3,\!57-4,\!17$	3.86	998742.34
5	$4,\!17-4,\!70$	3.60	812539.64
6	4,70 - 7,00	3.38	332004.76
7	7,00 - 8,62	2.58	235380.97
8	$8,\!62 - 10,\!0$	2.19	133574.46
9	10,0-20,0	1.93	117079.71
10	20,0 - 40,0	1.02	35189.94
11	40,0 - 70,0	0.52	9747.53
12	70,0 - 100	0.31	9747.53

Tabela D.1: Discretização "valor médio". Valores de $C_{o,j}$ e K_j aplicados à UDF para cada faixa de comprimento de onda.

$$\overline{a}_{soot,j} = K_j f_V, \tag{D-8}$$

onde

$$K_j = \frac{C_{o,j} \ln \left(\frac{\lambda_{j+1}}{\lambda_j}\right)}{\lambda_{j+1} - \lambda_j},\tag{D-9}$$

é um valor que depende apenas da faixa de comprimento de onda. A Tabela D.1 mostra os valores de $C_{o,j}$ e K_j para 12 faixas de comprimento de onda, as quais foram empregados na implementação da UDF no cálculo do coeficiente de radiação espectral, e, a Figura D.2 mostra a dependência com o comprimento de onda de C_{λ} e K_j , os quais foram calculados mediante as respectivas Equações (D-2) e (D-9).

D.3 Funções Definidas Pelo Usuário (UDF)

A seguir, são escritas, em linguagem C das UDFs, as implementações realizadas para o cálculo do coeficiente de absorção da fuligem aplicando-se a teoria de absorção/espalhamento de Rayleigh, e empregando-se as discretização "valor médio".

D.3.1

Implementação do Modelo Raileigh

A seguinte rotina permite calcular o coeficiente de absorção da fuligem segundo a teoria de absorção/espalhamento Rayleigh, aplicando-se a metodolo-

Figura D.2: Comparação entre os valores analíticos e de discretização de $C_{\lambda}(\lambda)$ e $K(\lambda) = C_{\lambda}(\lambda)/\lambda$ como função do comprimento de onda.

gia de discretização "Valor Médio".

Levantamento das Curvas de Vaporização para o n-heptano de n-dodecano(querosene)

A seguir apresentam-se as curvas de pressão de saturação do n-heptano e do n-dodecano, componentes representativos do querosene. Cabe ressaltar que o n-dodecano é o principal componente do querosene.

Estas curvas foram obtidos de equações semi-empíricas formuladas por Sazhin (2006) e das constantes fornecidas pelo NIST (*National Institute of Standards and Technology*) para a equação de Antoine,

$$\log_{10} p_s = A - \left(\frac{B}{T+C}\right),\tag{E-1}$$

onde p_s e T são a pressão de saturação (em bar) e a temperatura (em K) da substância, e onde A, B e C são parâmetros empíricos, específicos para cada substância. Assim, o NIST reporta das constantes A, B e C para o n-heptano e o n-dodecano, que foram obtidas do trabalho de Williamham *et al.* (1945), e que são apresentados na Tabela E.1.

Por outra parte, Sazhin (2006) compilou uma série de formulações semiempríricas de propriedades termodinâmicas do n-Tetradecano, n-heptano, ndodecano e Diesel, que descrevem a vaporização, ignição e quebra de gotículas destes combustíveis. Para o caso do n-heptano e do n-dodecano foram levantadas Sazhin (2006) as seguintes formulações semi-empíricas,

$$p_s = 10^{4,02677 - 1258,34/(T - 53,85)},\tag{E-2}$$

$$p_s = 6,894757 \times 10^{-5} \times e^{12,12767 - 3743,84/(T - 93,022)},$$
 (E-3)

onde p_s e T são a pressão de saturação e a temperatura expressa em bar e K, respectivamente. Note-se que a Equação (E-2) apresenta, para o n-heptano, a

Tabela E.1: Parâmetros empíricos da Equação de Antoine para o n-heptano e o n-dodecano obtidos do trabalho de Williamham *et al.* (1945).

HIDROCARBONETO	А	В	С
n-heptano	4,02832	1268,636	-56,199
n-dodecano	4,10549	1625,928	-92,839

Ε

Figura E.1: Curvas de pressão de saturação do n-heptano e do n-dodecano.

solução da equação geral de Antoine [Equação (E-1)], e onde os coefcientes A, B e C, reportados por Sazhin (2006) são muito semelhantes àqueles apresentados por Williamham et al. (1945).

A Figura E.1 mostra as curvas de vaporização obtidas das formulações de Sazhin (2006) [Equações (E-2) e (E-3)] e com os dados de A, B e C do NIST (Williamham et al., 1945) usados na Equação de Antoine [Equação (E-1)]. Nela mostra-se que, para o caso do n-dodecano, tanto a equação fornecida por Sazhin (2006) quanto os dados reportados pela NIST (Williamham et al., 1945) levam a uma mesma curva de saturação. Contudo, para o caso do n-heptano, as curvas de saturação da equação de Antoine [Equação (E-1)] apresentam pequenas discrepâncias.

De posse das curvas de pressão de saturação para o n-heptano e o ndodecano, é possível obter, para qualquer pressão, a temperaturas de ebulição. Além da curva de saturação do combustível empregado, é necessário fornecer ao FluentTM a temperatura de ebulição. Assim, a Tabela E.2 apresenta a temperatura de ebulição do n-heptano e do n-dodecano obtidas para 0, 1 e 0, 3 MPa.

Na simulação do queimador de Nakamura et al. (2011), o n-heptano é considerado como representativo das propriedades físicas do querosene. Desta forma, escolheu-se a formulação (E-3) para descrever a curva de saturação do n-heptano, resultando nas temperaturas de ebulição de 366, 4 e 408, 4 K para pressões de operação do queimador de 0, 1 e 0, 3 MPa, respectivamente.

Tabela E.2: Temperaturas de ebulição do n-heptano e do n-dodecano para 0, 1 e 0, 3 MPa, obtidas das formulações de Sazhin (2006) e dos dados reportados pelo NIST [Williamham *et al.* (1945)].

Pressão	n-heptano		n-dodeca	no
(MPa)	Sazhin (2006)	NIST	Sazhin (2006)	NIST
$_{0,1}$	$366,4 {\rm K}$	$371,2 { m K}$	489,1 K	489,0 K
$0,\!3$	$408,\!4~\mathrm{K}$	$413{,}5~\mathrm{K}$	$541,\!2~\mathrm{K}$	$541{,}0~\mathrm{K}$

Cabe ressaltar que uma vez que não se dispõe de modelo de cinética química de combustão do n-dodecano, também é empregado o modelo cinético de Wisconsin (Patel *et al.*, 2004) para a combustão do n-heptano.
